● HPLC Separation Modes

Liquid chromatography (LC) uses liquid as mobile phase (eluent). It is an analytical method that separates a mixture of compounds based on their physical and chemical differences. High performance liquid chromatography (HPLC) is a method that introduces the mobile phase under high-pressure conditions resulting in rapid and high-performance separations. The various interactions between the analyte, stationary phase (packing material), and mobile phase are the key factors for the separation. A wide variety of separation modes can be achieved by using particular combinations of stationary and mobile phases.

Separation mode	Characteristics
Reversed Phase Chromatography (RPC)	<ul style="list-style-type: none"> Separation is based on the partition equilibrium between stationary phase and mobile phase. The polarity of the stationary phase is lower than that of the mobile phase. Typically the mobile phase contains a mixture of organic solvents (methanol, acetonitrile, or THF) and aqueous solvents (water or buffer). Use of lower polarity mobile phases fasten the elution.
Hydrophilic Interaction Chromatography (HILIC)	<ul style="list-style-type: none"> Separation is based on hydrophilic interaction. A high polarity stationary phase is used. Typically the mobile phase contains a mixture of organic solvents such as acetonitrile and aqueous solvents (water or buffer). Using the higher polarity mobile phase causes a faster elution. Applicable for the analysis of high polar substances.
Normal Phase Chromatography (NPC)	<ul style="list-style-type: none"> Separation is based on the partition equilibrium between the stationary phase and the mobile phase. The polarity of the stationary phase is higher than that of the mobile phase. Typically the mobile phase contains a mixture of organic solvents with different polarities such as hexane and isopropanol. Using the higher polarity mobile phase causes a faster elution.
Ligand Exchange Chromatography (LEX)	<ul style="list-style-type: none"> Separation is based on differences in analytes' coordination complex. Stationary phase modified with metal sulfonate complex ion. Works in combination with size exclusion or HILIC modes.
Ion Exclusion Chromatography (IEX)	<ul style="list-style-type: none"> Separation is based on electrostatic interaction (repulsion) between the ion exchanger and ionic solutes. Dissociated ionic molecules elute faster than non-dissociated forms. Used mainly for the analysis of organic acids.
Ion Chromatography (IC)	<ul style="list-style-type: none"> Separation is based on electrostatic interaction (bonding) between the ion exchanger and ionic solutes. Electrical conductivity detector can be used with a mobile phase with low-salt concentration. Used mainly for the analysis of inorganic compounds.
Size Exclusion Chromatography (SEC)	<ul style="list-style-type: none"> Network or pores on the surface of the packing material works as molecular sieve to separate molecules based on their sizes. To separate molecules solely based on their sizes, it requires an analytical condition without any analyte and packing gel interaction. The bigger the molecule size, the faster the elution sequence. Used for molecular weight or molecular distribution determination of macromolecules and qualification of oligomers.
Ion Exchange Chromatography (IEC)	<ul style="list-style-type: none"> Separation is based on electrostatic interactions between the ion exchanger and ionic solutes. The mobile phase of choice should have a sufficient buffering capacity at the pH that produces the largest charge differences between the analyte of interest. The elution position is optimized by varying the pH, salt concentration, and/or ionic strength of the mobile phase.
Hydrophobic Interaction Chromatography (HIC)	<ul style="list-style-type: none"> Separation is based on hydrophobic interaction. Hydrophobic functional group is modified on the stationary phase. Adsorption of analytes generally occurs at a high salt concentration and they are released by lowering the salt concentration. Used mainly for the analysis of proteins.
Affinity Chromatography (AFC)	<ul style="list-style-type: none"> Separation is based on adsorption of the analyte to the specific biologically derived ligand pair. Highly selective. A buffer solution with the appropriate pH and ionic strength is selected based on the type of ligand, analytes, and their interaction. Used mainly for the purification and concentration of biologically active substances.
Chiral Separation Chromatography (CS)	<ul style="list-style-type: none"> Separation of optical isomers using chiral selectors. Highly selective.
Multimode Chromatography	<ul style="list-style-type: none"> Separation is based on the combination of different modes.

The interrelation between hydrophobicity and retention, and the interrelation between steric selectivity and retention were compared among Shodex columns for reversed phase chromatography.

The retention factor (k') of amylbenzene was used as the retention, the separation factor (α) between n-butylbenzene and n-amino benzene was used as the hydrophobicity. The separation factor between o-terphenyl and triphenylene was used as the steric recognition.

Lager separation factor means higher hydrophobicity and higher steric selectivity.

Influence of repeated protein injection on column pressure

ODP2 HP columns are packed with gels with increased surface polarity and smaller pore size which prevent the adsorption of proteins.
 BSA was injected multiple times to both ODS and ODP2 HP columns.
 A significant column pressure increase was observed for the ODS column, while no considerable change was observed for the ODP2 HP column even after 140 injections.

Comparison of barbital recovery rate using ODP2 HP-2B and ODS in the presence of BSA

For the LC/MS analysis of drugs in samples containing protein matrix, use of ODP2 HP column showed less matrix effect (ion suppression in this case) compared to when ODS column was used. This shows that ODP2 HP column does not retain protein and elute it as a void.

 Flow rate : 0.2mL/min

Local anesthetics

Dissociation of tertiary amino groups in basic drugs can be suppressed by making pH of the eluent higher than pKa of the amino groups. This increases the relative hydrophobicity of the basic drugs, thereby allowing the column to retain the drugs stronger and provide baseline separation of them.

Recovery of reducing sugar

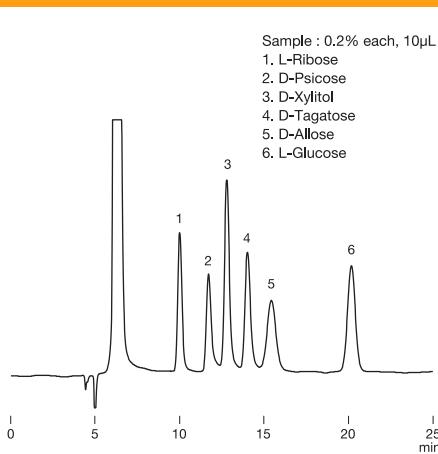

When an amino column is used for analyzing saccharides, the recovery ratio of reducing saccharides such as mannose, arabinose or xylose is low because the amino group forms Schiff base with reducing saccharides. HILICpak VG-50 is an amino column with improved reducing saccharides' recovery ratios. Improved recovery ratio results in enhancing the sensitivity of the analysis.

Simultaneous analysis of saccharides, organic acids and amino acids with LC/MS

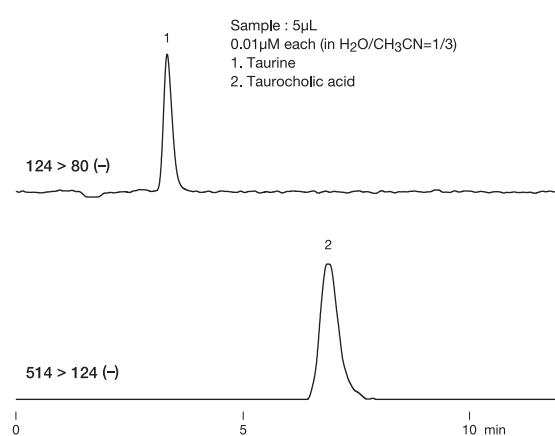

Sample : 1μg/mL each (in $\text{H}_2\text{O}/\text{CH}_3\text{CN}=1/4$), 5μL

VG-50 2D allows simultaneous analysis of saccharides, organic acids and amino acids with LC/MS detection under alkaline conditions. High anionic substances elute under alkaline conditions. Furthermore, alkaline conditions promote the deprotonation of hydroxyl groups at the time of ionization. Therefore, alkaline conditions are suitable for high sensitive detection of substances with hydroxyl groups such as saccharides under the negative mode.

Saccharides anomer separation

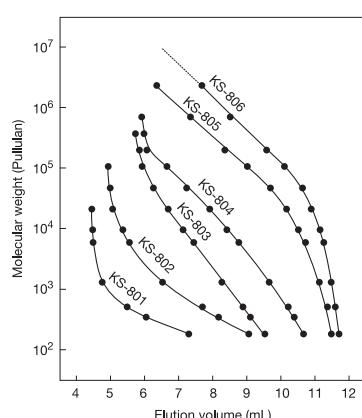

Saccharides may present their anomers at lower temperatures. By setting the SUGAR series columns at higher temperatures will prevent the anomer separation and this results in providing better chromatograms of each saccharide.

Mannitol and sorbitol

Partial modifications on the analytical conditions of mannitol stated in the United States Pharmacopeia (USP, USP37-NF32) became effective on December 1st, 2014. Now for the separation of mannitol and sorbitol, USP, European Pharmacopoeia (EP), and Japanese Pharmacopoeia (JP) request to use a column having resolution more than 2.0. SC1011-7F fulfills the conditions required from USP, EP, and JP.

Precautions for Polar Polymer Analysis

Unexpected interactions in the column can affect the size exclusion chromatography analysis of polar polymers. These interactions may change elution patterns and results in an invalid molecular weight calculation. It is important to reduce these interfering interactions in order to obtain the accurate molecular weight distribution.

Interfering interactions likely to be observed

Interactions between the analyte and the packing materials

Hydrophobic interaction

- The analyte is adsorbed on the packing material. This delays the analyte elution and results in under estimating the analyte's molecular weight. See (B) and (D).

Ionic interaction

(1) Ion Exclusion

- The analyte is repelled from the packing material. This accelerates the analyte elution and results in over estimating the analyte's molecular weight. See (A) and (C).

(2) Ion Exchange

- The analyte is adsorbed on the packing material. This delays the analyte elution and results in under estimating the analyte's molecular weight. See (B) and (D).

Interaction within and between the analyte

Ionic repulsion effects observed within the multivalent macromolecules causes structure expansion

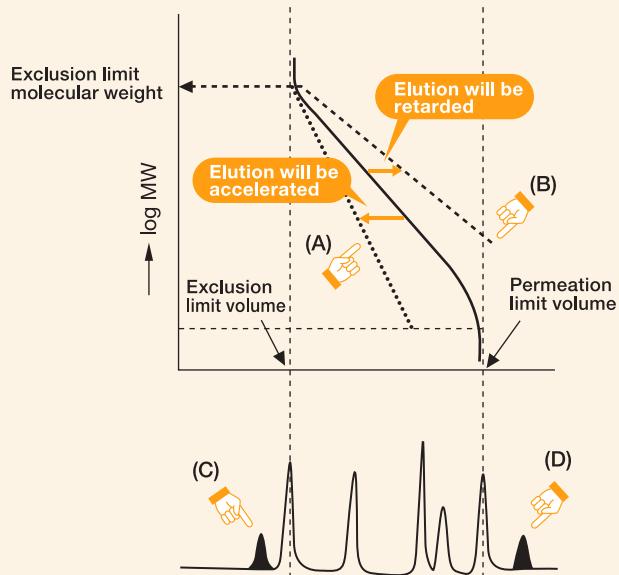

- This accelerates the analyte elution and results in over estimating the analyte's molecular weight. See (A).

Association between the molecules

- This accelerates the analyte elution and results in over estimating the analyte's molecular weight. See (A).

Interactions between the analyte and the solvent

The multivalent ion in the solvent works as a bridge to bind ionic molecules (analyte).

Methods to reduce interactions

Aqueous SEC (GFC)

Ionic Interaction

Add salt

Hydrophobic interaction

Increase the analyte dissociation

Cationic polymer → Lower the pH
Anionic polymer → Higher the pH

Lower the eluent polarity

(Example) Add acetonitrile or methanol

Organic solvent SEC (GPC)

Ionic Interaction

Add salt

(Example) Add LiBr to DMF
Add CF₃COONa to HFIP

Hydrophobic interaction

Lower the eluent polarity

(Example) Change the eluent from DMF to THF

Hydrophilic interaction

Increase the eluent polarity

(Example) Change the eluent from THF to DMF

Monitoring papain digestion of humanized monoclonal IgG

Sample : 10 μ L Humanized monoclonal IgG
 1. Aggregates of IgG
 2. Dimer of IgG
 3. Monomer of IgG
 4, 5, 6. Fragments of IgG from papain digestion
 7. Citric acid
 8. Papain

Papain digestion of humanized monoclonal IgG was monitored using PROTEIN LW-803, an aqueous SEC (GFC) column. During the papain digestion of IgG, Fc and Fab fragments from the IgG and their decomposition intermediates are expected to be observed. LW-803 separates IgG and decomposed fragments and intermediates well from each other, thus it is suitable for the monitoring of papain digestion of IgG.

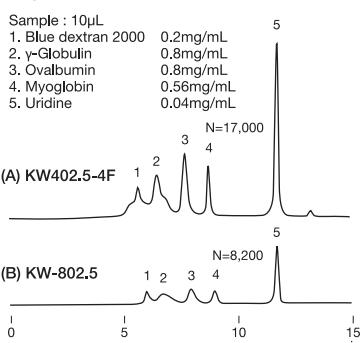

[Procedure of papain digestion]

- (1) Dissolve 3mg of humanized monoclonal IgG in 500 μ L of the eluent. (6mg/mL conc.)
- (2) Dissolve 1mg of papain in 500 μ L of the eluent. (1mg/mL conc.)
- (3) Pass (1) and (2) through 0.2 μ m membrane filter.
- (4) Mix each solution in equal amounts.
- (5) Keep temperature at 25°C.
- (6) Takes a sample with time and analyze it by HPLC.

Effects of sodium nitrate in eluent on the analysis of polyallylamine

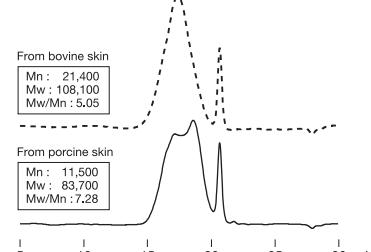

For the analysis of cationic polymers, such as polyallylamine, undesired adsorption of the polymer is observed when low (0.02M) sodium nitrate eluent was used. By using higher concentration (> 0.1M) salt, it suppresses the sample adsorption and enables to obtain accurate chromatograms.

Peptides

GS-HQ columns work not only under SEC (GFC) mode, but also under multimode, adding hydrophobic and ionic interactions. By carefully selecting the eluent, they provide separation mode that was not available with other types of columns. GS-320 HQ shows excellent performance separating hydrophilic peptides, particularly for acidic and basic peptides.

Analysis of purine bases in beer

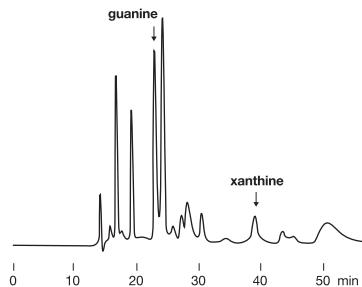

Purine in food is analyzed as purine base after steps of sample preparation: homogenization, freeze drying, hydrolyzation with 70% perchloric acid, and neutralization. Example below shows the analysis of purine in regular beer and beer treated with guanase (an enzyme that degrades guanine to xanthine). The following data indicate that guanine was decreased and xanthine was increased by guanase.

Low molecular weight water-soluble dietary fiber

GS-220 HQ allows to elute monosaccharides, disaccharides, and sugar alcohols after the indigestible component fraction (indicated by an arrow on the chromatogram). This separation makes the method preferable for the quantification of low molecular weight water-soluble dietary fiber.

Sodium polystyrene sulfonates

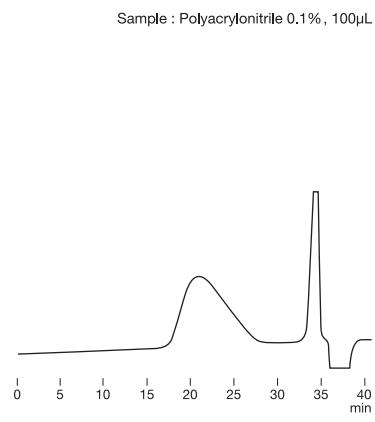

Polymers having both hydrophobic and hydrophilic functional groups may exhibit hydrophobic interactions with packing materials. When analyzing such polymers, addition of organic solvents to the eluent can suppress the hydrophobic interaction.

Polyacrylonitrile**Comparison of two GF column performances for the separation of maltooligosaccharides**

GF-210 HQ demonstrates an improved separation of low molecular substances. The chromatograms below show that the peaks obtained by GF-210 HQ are separated with deeper notches compared to peaks obtained by GF-310 HQ. GF-210 HQ is capable of separating oligosaccharides (trisaccharides to hexasaccharides) while those oligosaccharides were eluted all together when analyzed by GF-310 HQ.

Comparison of standard, rapid analysis, and high performance type columns

Standard type

KF-802.5 x 2
50µL injection

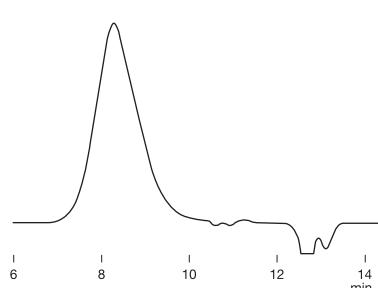

Sample : EPON1001 0.2%

KF-602.5 provides rapid analysis by reducing the analysis time; less than half of the analysis time of KF-802.5. Having 1.5 times more theoretical plate number than standard column, KF-402.5HQ provides improved resolution especially for the separation of small to medium molecular weight substances. Rapid analysis and high performance type columns use less than one third of solvent per analysis compared to standard type columns do.

Effects of gel particle size in high temperature GPC columns

High temperature GPC columns are suitable for the analysis of high molecular weight polymers that are difficult to be dissolved in ambient temperature solvents; examples of such polymers are polyethylene and polypropylene. The GPC UT-800 series packed with large particle size (30μm) are recommended for the analysis of macromolecules. The large particle size prevents potential molecular shear degradation of the sample.

2. High density polyethylene (HDPE-A)

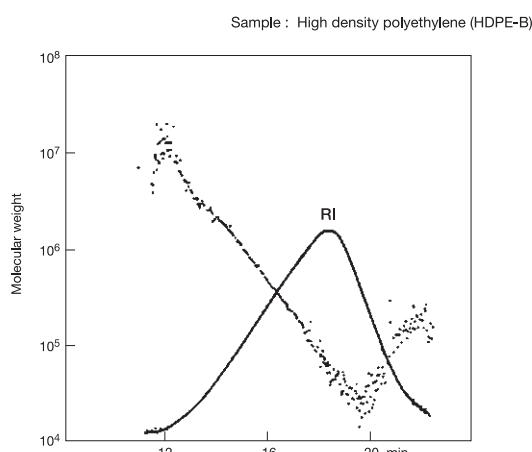

Column : UT-806M x 3

Column Cleaning Procedures

Change in peak shapes, elution timing, and the elevated column pressure may be resolved by cleaning the column. This section describes general indications of column deterioration and column cleaning procedures. For detailed column cleaning procedures, refer to operating manual packaged with each column.

■ Typical indicators of column deterioration

1. Elevated column pressure
2. Abnormal peak shapes (broadening, leading, or tailing) and split peaks
3. Change in retention time
4. Unstable baseline

■ Cleaning solvent selection guide

Solvents capable of dissolving the adsorbed substances

Solvents with high eluting power (variable depending on separation mode)

*Use the solvent specified in the operation manual.

■ Standard cleaning procedures

For an efficient cleaning, reverse the direction and reduce the flow rate to 1/3 of the regular flow.

Reversed phase chromatography columns	Clean the columns with solvent containing higher concentration of organic solvent such as methanol, acetonitrile, or THF. (In case of using buffer as a mobile phase, miscibility of the buffer solution and the organic solvents need to be checked)
Sugar analysis columns	[Ligand exchange columns (SUGAR series)] <ul style="list-style-type: none">• In case of counter ion detachment Flush or inject solvent containing the salt corresponding to the modified counter-ligand.[Polymer-base amino columns (NH2P series)]<ul style="list-style-type: none">• In cases where an acidic substance has been bound to the amino functional group Flush with solvents in the following sequence: water, 0.1M perchloric acid (aq.), water, 0.1M NaOH (aq.), water, and mobile phase.
Aqueous SEC (GFC) chromatography columns	<ul style="list-style-type: none">• In cases where an ionic substance has been adsorbed Use a solvent with higher salt concentration or solvent with different pH from the mobile phase.• In cases where a hydrophobic substance has been adsorbed Use a solvent containing organic solvent. (In case of using buffer as a mobile phase, miscibility of the buffer solution and the organic solvents need to be checked)
Ion exchange chromatography columns	<ul style="list-style-type: none">• In cases where an ionic substance has been adsorbed Use a solvent with higher salt concentration or solvent with different pH from the mobile phase.• In cases where a hydrophobic substance has been adsorbed Use a solvent containing organic solvent. (In case of using buffer as a mobile phase, miscibility of the buffer solution and the organic solvents need to be checked)• In cases where protein have been adsorbed Inject 1-2 mL of 0.1 M NaOH (aq.) or 30% (v/v) acetic acid (aq.) several times.
Hydrophobic interaction chromatography columns	<ul style="list-style-type: none">• In cases where protein have been adsorbed Inject 1-2 mL of 0.1 M NaOH (aq.) or 30% (v/v) acetic acid (aq.) several times.

*The volume of the cleaning solvent required is 5-10 times the column volume.

*Avoid pressure elevation during the cleaning.

*The cleaning is limited and does not guarantee the full regeneration of the column to its original condition.

■ For your information

One typical cause of the column pressure elevation is the solid substance being clogged at the inlet filter of the column. In this case, reverse the direction and reduce the flow to 1/3 of the regular flow rate. This may remove the solid substance causing the elevated pressure.

*Use the solvent specified in the operation manual.

General Precautions for Column Handling

For the best performance of the column, please follow the instructions given below.

■ Column mounting

- Before mounting the column, replace the eluent within all the HPLC system with the mobile phase used for the analysis. *If the mobile phase of the choice is not miscible with the eluent already in the system, use solvent that is miscible with both solvents first to clean the system. *Buffer or salt solution may precipitate when mixed with organic solvent of different concentrations.
- Attach the column in the direction as indicated by arrow marked on the column. Gradually increase the flow rate of the solvent introduced to the column.
- When heating the column, be sure to pump the eluent at a low flow rate until the specified temperature is reached, and then gradually increase the flow rate up to the requirement after the column has been heated sufficiently.

■ Column dismounting

- If the column is heated, turn off the heater while keeping the flow rate at 1/3 of the regular flow.
- Turn off the pump when the column is cooled to room temperature.
- Remove the column from the system securely tighten the end caps.

■ Column storage

- For long-term storage, replace the solvent with shipping solvent and securely tighten the end caps.
- Store the column in a location with stable temperature.
- For long-term storage of SEC columns, immersion method is recommended.
*Please refer to the immersion method on the operation manual.

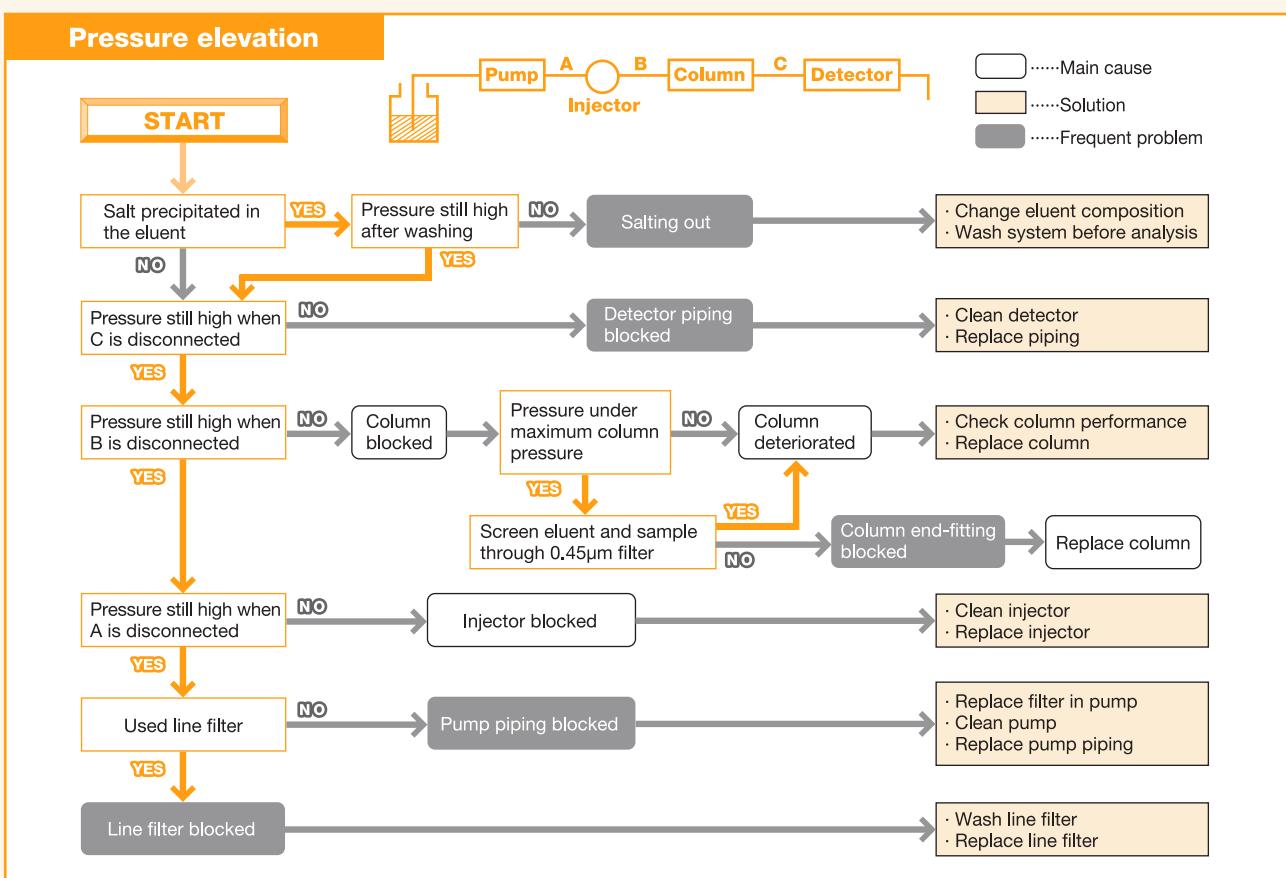

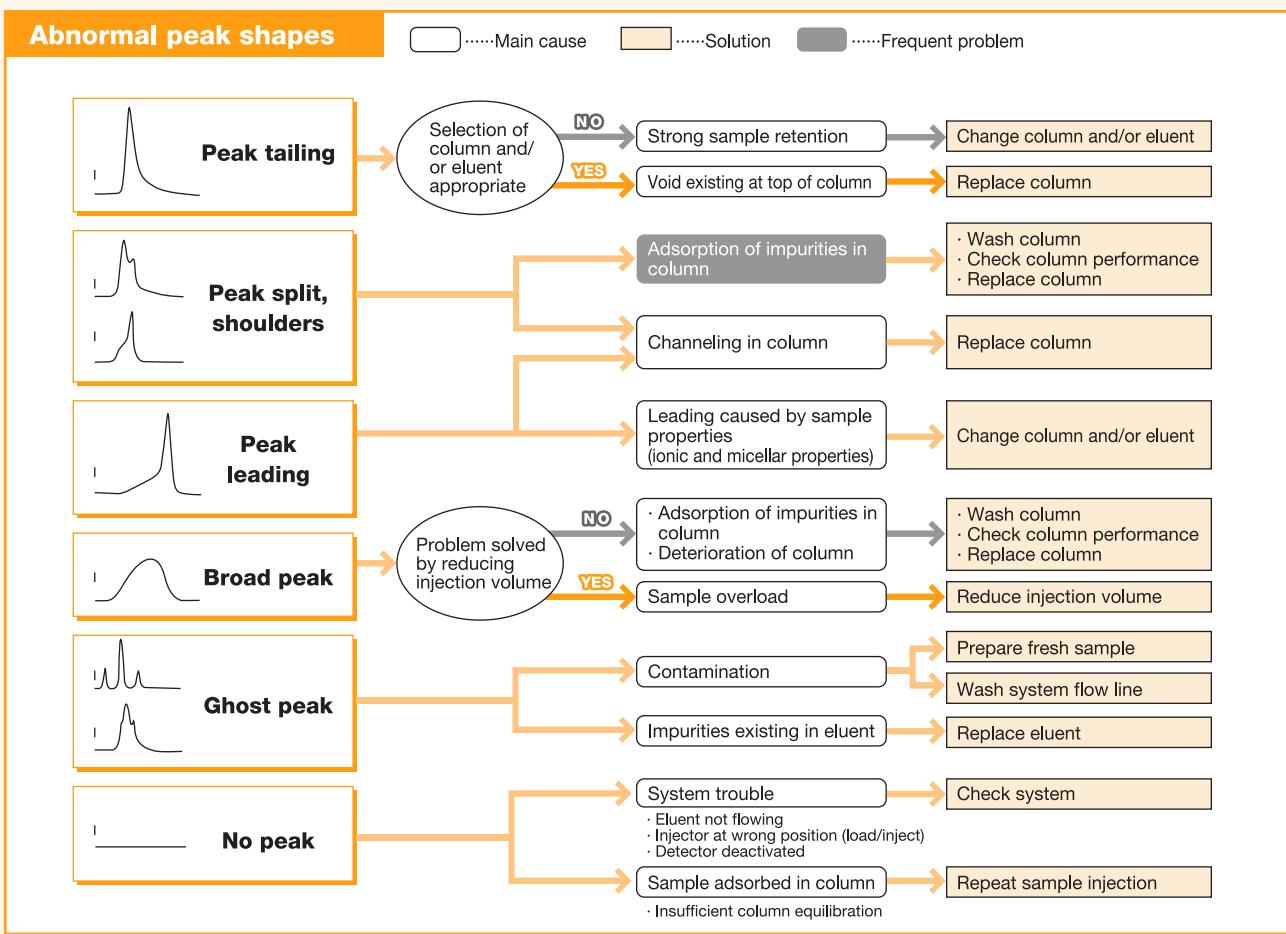

■ Other

- Avoid physical shock on the column. Be cautious not to drop the column from a high position.
- Do not bend the column.
- Avoid opening the column's end-fitting, it can cause alteration of column's performance.

*Read the operation manual before using the column.
